Modern day communication increasingly takes place over digital networks. Many digital networks allow the transport of data in the form of analog electrical signals. One popular digital network is asynchronous transfer mode (ATM) network. An ATM switch has a plurality of ports (e.g., transmitters) each having a port buffer that is used to store the analog signals arriving on the port. As data arrives on a port, the port buffer stores the data until a sufficient quantity of the data has accumulated to be transmitted on the network. A problem arises when a physical or electrical disturbance occurs at the transmitting end of the network (e.g., a switch) which causes the data to be accumulated in a non-optimum manner in the port buffer. For instance, if there is a brief electrical or a physical disturbance at the transmitting end, the data in the buffer is scattered and often accumulated in a slow or a fast manner. This causes the data at the receiving end of the network to appear as jitter. For the purpose of the present discussion, jitter is defined as any non-periodic disturbance that appears to the eye to be random. Even a single isolated pulse (e.g., a gamma ray burst) may cause jitter in a signal stream if enough energy is accumulated on a given sample interval. Jitter is a major factor limiting the performance of many digital networks and electronic systems. If the amount of jitter is too high, electronic circuits may not be able to react to the incoming data and thus they may fail to read the data accurately. For instance, in a modem, data is read from a source and is written to a destination before it is output on the digital network (e.g., a telephone network). Jitter disturbs the rate at which the data is read from the source and thus disturbs the rate at which the data is written to the destination. Consequently, the data provided to the network may be inaccurate and thus may fail to be transmitted accurately over the network. The amount of jitter that may be tolerated by a digital network is dependent upon the accuracy of the electronic circuits that process the data received on the network. The accuracy of the electronic circuits that process the data may be increased by reducing the amount of jitter in the data. Reducing the amount of jitter may be accomplished by adjusting the rate of acquisition of the incoming data. For instance, in order to reduce the jitter in a modem system, the data may be acquired at a slower rate than the rate at which

Q: Qual is the difference between IoT and M2M I am trying to explain what IoT and M2M means in the mind of a non-technical person with the help of an example. I know that IoT is something that connects physical things with digital connected to the internet like computer, Smart TV, etc. On the other hand, M2M stands for Machine to Machine, the same as IoT except it is a physical object. But, I don't understand the difference between IoT and M2M, because the concept of IoT is inherently related to M2M. Can someone explain this difference with an example. A: It seems you are using "IoT" and "M2M" to mean the same thing. I think the differences you have in mind are these. IoT stands for Internet of Things. This is used to refer to the use of things you can find on the Internet. M2M stands for Machine to Machine. This is used to refer to two devices communicating on their own. Often machines do not need a device designed specifically for their communication. See As you suggest, these definitions are inherently related, but I prefer to use the term "IoT" when referring to things that can communicate, as "Internet of Things" is a term that comes more naturally to a non-technical person than "Machine to Machine." I also feel that many IoT devices like smart phones are interconnected in a way that they can communicate with each other, so I prefer to use the term "Internet of Things" for these devices as well. A new class of dendrimer-like polymers as efficient electrocatalysts for the oxidation of hydrogen peroxide. A new class of dendrimer-like materials consisting of a polypropylene branch as a linker and a three-dimensional polyaniline (3D-PANI) core as an electrochemical active linker was synthesized via a bromoalkene polymerization, in which the polymerization was carried out in aqueous media and the resulting polymers were purified using an ion-exchange resin. The first-principle calculations revealed that both the external and the internal PANI layer have many valence states. It is possible to control and optimize the electronic properties of the
